

A Case of Septum Pellucidum Agenesis in A Patient with Psychotic Symptoms

Agenesis of the septum pellucidum is a rare congenital defect that has been associated with psychiatric disorders, cognitive deficits, learning disabilities, seizures and neuropsychiatric disturbances. We present the case of a patient with partial agenesis of the septum pellucidum who exhibits disorganized behavior, paranoid and persecutory delusions. We add to the literature of incidental neuropsychiatric symptoms in patients with partial agenesis of the septum pellucidum which is an area that requires further exploration and study. We discuss the implications of these findings in light of previous literature findings.

On the Pathogenesis of Multiple Personality Disorders: A Case of Three Multiple Personality Patients and Literature Review

The pathogenesis of multiple personality disorder continues to remain an area of research with precipitating factors such as neurobiological and psychosocial factors being explored. There is no clear theory of the emergence of the symptomatology of multiple personality disorders following precipitating factors. We explore a possible pathogenesis of multiple personality disorders based on psychological principles. The theory is based on observations of the psychological development of three cases with multiple personality disorders. The commonalities in these cases motivate the exploration of the interplay of cognitive imitation, introjection and traumatic experience in the emergence of multiple personality disorders.
